### OS Archaeology (contd.)

#### Linus Torvalds

- **Linux** → Android OS, Chrome OS
- **Linux** → RedHat, Ubuntu, Fedora, Debian, Suse, ...

## Warm-up

### OS Archaeology (contd.)

#### Steve Jobs

- Mach + BSD → NextStep → XNU → Apple OSX, iPhone **iOS**

## Warm-up

### OS Archaeology (contd.)

#### Bill Gates

- CP/M → QDOS → **MS-DOS** → **Windows** 3.1 → NT → 95 → 98  
→ 2000 → XP → Vista → 7 → 8 → 10 → phone, ...

## Warm-up

### Discussion

- What Operating System(s) are you familiar with?
- What is the best Operating System in your opinion? And for what features?

## Objectives

- To describe the basic organization of computer systems.
- To explain the evolution of operating system structures.
- To provide a grand tour of the major components of operating systems.
- To give an overview of the many types of computing environments.
- To explore several open-source operating systems.

# What Operating Systems Do

## *What is an Operating System?*

- A **program** that acts as an intermediary between a user of a computer and the computer hardware.
- Operating system goals:
  - Execute user programs and make solving user problems **easier**.
  - Make the computer system **convenient** to use.
  - Use the computer hardware in an **efficient** manner.

# What Operating Systems Do

## Computer System Structure

Computer system can be divided into four components:

- **Hardware** — provides basic computing resources.
  - CPU, memory, I/O devices
- **Operating system** — controls and coordinates use of hardware among various applications and users
- **Application programs** — define the ways in which the system resources are used to solve the computing problems of the users.
  - Word processors, compilers, web browsers, database systems, video games
- **Users**
  - People, machines, other computers

# What Operating Systems Do

## Computer System Structure (contd.)

- We can explore operating systems from two viewpoints: that of the **user** and that of the **system**.

# What Operating Systems Do

## User View

- Want **convenience**, **ease of use** and **good performance**.
- Don't care about **resource utilization**.
  - But *shared computer* such as *mainframe* or *minicomputer* must keep all users happy.
  - Users of *dedicate systems* such as *workstations* have dedicated resources but frequently use shared resources from *servers*.
  - Handheld computers are resource poor, optimized for usability and battery life.
  - Some computers have little or no user interface, such as embedded computers in devices and automobiles.

# What Operating Systems Do

## System View

- OS is a **resource allocator**.
  - Manages all resources.
  - Decides between conflicting requests for efficient and fair resource use.
- OS is a **control program**.
  - Controls execution of programs to prevent errors and improper use of the computer.

# What Operating Systems Do

## Defining Operating Systems

- **No universally accepted definition.**
- “Everything a vendor ships when you order an operating system”
  - is a good approximation,
  - but varies wildly.
- “The one program running at all times on the computer”
  - defines the kernel,
  - everything else is either
    - » a system program (ships with the operating system) , or
    - » an application program.

# Computer-System Organization

## Computer Startup

- **Bootstrap program** is loaded at power-up or reboot.
  - Typically stored in ROM or EPROM, generally known as firmware.
  - Initializes all aspects of system.
  - Loads operating system kernel and starts execution.
- Think of:
  - What happens when a program runs / How instructions are executed?
  - Millions/billions of times a second,
    - » the processor fetches an instruction from memory,
    - » decodes it,
    - » executes it,
    - » moves on to the next till end.

# Computer-System Organization

## Von Neumann Model

- We have just described the basics of the **Von Neumann model** of computing.
- “...an electronic digital computer with parts consisting of
  - a processing unit containing an arithmetic logic unit and processor registers;
  - a control unit containing an instruction register and program counter;
  - a memory to store both data and instructions;
  - external mass storage; and
  - input and output mechanisms.”
    - Wikipedia “Von Neumann architecture”.

# Computer-System Organization

## *Von Neumann Model (contd.)*

The above Von Neumann Model defines/describes:

- How is a computer-system organized
  - One or more CPUs, device controllers connect through common bus providing access to shared memory.
- How is a computer-system operating
  - Concurrent execution of CPUs and devices competing for memory cycles.

# Computer-System Organization

## Computer-System Operation

- I/O devices and the CPU can execute **concurrently**.
- But how?
  - Each device controller is in charge of a particular device type.
  - Each device controller has a local buffer.
  - CPU moves data from/to main memory to/from local buffers.
  - I/O is from the device to local buffer of controller.
- By now communication is enabled, but how to cooperate?
  - Device controller informs CPU that it has finished its operation by causing an **interrupt**.

# Computer-System Organization

## *Common Functions of Interrupts*

- An interrupt is an input signal to the processor indicating an event that needs immediate attention.
- Interrupt transfers **control** to the interrupt service routine generally, through the **interrupt vector**, which contains the addresses of all the service routines.
- Interrupt architecture must save the address of the interrupted instruction.
- A **trap** or **exception** is a software-generated interrupt caused either by an error or a user request.
- An operating system is **interrupt driven**.

# Computer-System Organization

## Interrupt Handling

- The operating system preserves the state of the CPU by storing registers and the program counter.
- Determines which type of interrupt has occurred:
  - polling, or
  - vectored interrupt system
- Separate segments of code determine what action should be taken for each type of interrupt.

# Computer-System Organization

## Interrupt Timeline

# Computer-System Organization

## Storage-Device Hierarchy

# Computer-System Organization

## Storage Structure

- Main memory — only large storage media that the CPU can access directly.
  - Random access.
  - Typically volatile.
- Secondary storage — extension of main memory that provides large nonvolatile storage capacity.
- Hard disks — rigid metal or glass platters covered with magnetic recording material.
  - Disk surface is logically divided into tracks, which are subdivided into sectors.
  - The disk controller determines the logical interaction between the device and the computer.
- Solid-state disks — faster than hard disks, nonvolatile.
  - Various technologies.
  - Becoming more popular.

# Computer-System Organization

## An Example of I/O Interrupts

(a) No interrupts

(b) Interrupts; short I/O wait

(c) Interrupts; long I/O wait

# Computer-System Organization

## *I/O Structure — No Interrupts*

- After I/O starts, control returns to user program only upon I/O completion
  - Wait instruction idles the CPU.
  - Wait loop (contention for memory access).
  - At most one I/O request is outstanding at a time, no simultaneous I/O processing.

# Computer-System Organization

## *I/O Structure — Interrupt Driven*

- After I/O starts, control returns to user program without waiting for I/O completion
  - **System call** — request to the OS to allow user to wait for I/O completion.
  - **Device-status table** contains entry for each I/O device indicating its type, address, and state.
  - OS indexes into I/O device table to determine device status and to modify table entry to include interrupt.
- Who returns the control?
  - **Device Driver** for each device controller to manage I/O. Provides uniform interface between controller and kernel.

# Computer-System Organization

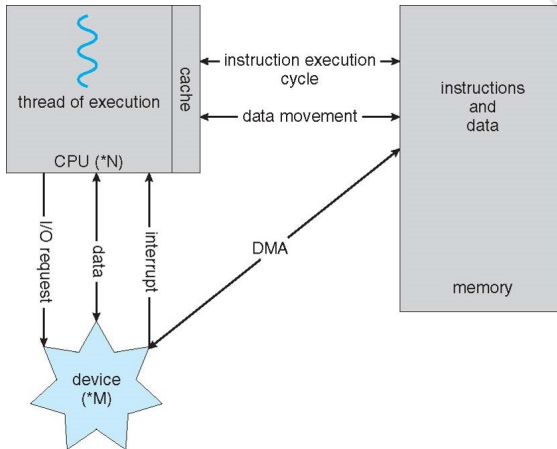

## *I/O Structure — Direct Memory Access*

- **Direct Memory Access** Structure
  - Used for high-speed I/O devices able to transmit information at close to memory speeds.
  - Device controller transfers blocks of data from buffer storage directly to main memory without CPU intervention.
  - Only one interrupt is generated per block, rather than the one interrupt per byte.

## Computer-System Architecture

- Most systems use a single general-purpose processor until 10 years ago.
  - Most systems have special-purpose processors as well.
- **Multiprocessor** systems growing in use and importance.
  - Also known as **parallel systems**, **tightly-coupled systems**.
  - Advantages include:
    1. Increased throughput.
    2. Economy of scale.
    3. Increased reliability — graceful degradation or fault tolerance.
  - Two types:
    1. **Asymmetric Multiprocessing** — each processor is assigned a specific task.
    2. **Symmetric Multiprocessing** — each processor performs all tasks.

# Computer-System Architecture

## Symmetric Multiprocessing Architecture

# Computer-System Architecture

## A Dual-Core Design

- Multi-chip and **multicore**.
  - Why multicore?
  - On-chip communication is faster, uses significantly less power.
- Blade Servers: all in one chassis.
  - Chassis containing multiple separate systems.

# Computer-System Architecture

## Clustered Systems

- Like multiprocessor systems, but multiple systems working together.
- Loosely-coupled systems.
  - Usually sharing storage via a storage-area network (SAN).
  - Provides a **high-availability** service which survives failures.
    - » Asymmetric clustering has one machine in hot-standby mode.
    - » Symmetric clustering has multiple nodes running applications, monitoring each other.
  - Some clusters are for **high-performance** computing (HPC).
    - » Applications must be written to use parallelization.
  - Some have distributed lock manager (DLM) to avoid conflicting operations.

# Operating-System Structure

## Some History

- No operating system. (1946 ~ 1955, ENIAC)
- A typical simple **Batch system** (since 1950s)
  - bring cards to IBM 1401
  - IBM 1401 read cards to tape
  - put tape on IBM 7094 which does computing
  - put tape on IBM 1401 which prints output

# Operating-System Structure

## Some History (contd.)

- **Multiprogramming** (Batch system) needed for efficiency. (since 1960s)
  - Single user cannot keep CPU and I/O devices busy at all times.
  - Multiprogramming organizes jobs (code and data) so CPU always has one to execute.
  - A subset of total jobs in system is kept in memory.
  - One job selected and run via **job scheduling (long term scheduling)**.
  - When it has to wait (for I/O for example), OS switches to another job.

# Operating-System Structure

## *Some History (contd.)*

- **Timesharing** (multitasking, since 1960s) is logical extension in which CPU switches jobs so frequently that users can interact with each job while it is running, creating **interactive** computing.
  - **Response time** should be  $< 1$  second.
  - Each user has at least one program executing in memory — **process**.
  - If several jobs ready to run at the same time — **CPU scheduling** (**short term scheduling**).
  - If processes don't fit in memory, **swapping** moves them in and out to run.
  - **Virtual memory** allows execution of processes not completely in memory.

## In Class Exercise

### Multiprogramming

- Consider a multiprogramming environment, two programs A and B share the system simultaneously, and run as follows. Suppose B runs first,  $I/O_A$  and  $I/O_B$  are different devices, and the time of switching between A and B can be ignored. Draw the timeline for these two programs, and calculate CPU utilization within 60 minutes.
- What if  $I/O_A$  and  $I/O_B$  are the same device?

## In Class Exercise

### Key to Multiprogramming

Key to Q1: CPU utilization =  $50/60 = 83.33\%$

# Operating-System Operations

*Interrupt Driven (hardware and software)*

- Hardware interrupt by one of the devices.
- Software interrupt (**exception** or **trap**):
  - Software error (e.g., division by zero).
  - Request for operating system service.
  - Other process problems include infinite loop, processes modifying each other or the operating system.

# Operating-System Operations

## Dual Mode

- **Dual-mode** operation allows OS to protect itself and other system components.
  - **User mode** and **kernel mode**.
  - **Mode bit** provided by hardware.
    - » Provides ability to distinguish when system is running user code or kernel code.
    - » Some instructions designated as **privileged**, only executable in kernel mode.
    - » **System call** changes mode to kernel, return from call resets it to user.
- Increasingly CPUs support multi-mode operations.
  - i.e., **virtual machine manager (VMM)** mode for guest **VMs**.

# Operating-System Operations

## Dual Mode (contd.)

### Transition from User to Kernel Mode

# Operating-System Operations

## Timer

- **Timer** to prevent infinite loop / process hogging resources.
  - Timer is set to interrupt the computer after some time period.
  - Keep a counter that is decremented by the physical clock.
  - Operating system set the counter (privileged instruction).
  - When counter zero generate an interrupt.
  - Set up before scheduling process to regain control or terminate program that exceeds allotted time.

# Operating-System Operations

## What Happens When the Computer System is Booting?

### OS @boot (kernel mode)

---

initialize trap table

### Hardware

remember addresses of ...  
system call handler  
timer handler  
illegal instruction handler

start interrupt timer

start timer; interrupt after X ms

# Operating-System Operations

## What Happens When the Computer System is Running?

OS @run (kernel mode)	Hardware	Program (user mode)
to start process A: <i>return-from-trap</i> (into A)		
	move to <i>user mode</i>	
		process A runs: fetch instruction execute instruction ...
	timer interrupt move to <i>kernel mode</i> jump to interrupt handler

## *Too Many Terms?*

- Just remember three key ideas for now:
  - **Virtualization**: The OS takes a physical resource (such as the processor, or memory, or a disk) and transforms it into a more general, powerful, and easy-to-use virtual form of itself.
  - **Concurrency**: Many problems arise, and must be addressed, when working on many things at once (i.e., concurrently) in the same program.
  - **Persistence**: The OS makes information persist, despite computer crashes, disk failures, or power outages.

## Kernel Data Structures

*You Should Have Known the Concepts of ...*

- lists, stacks, and queues,
- trees,
- hash functions and maps,
- bitmaps.

# Computing Environments

## *Traditional Computing*

- Stand-alone general purpose machines.
- But blurred as most systems interconnect with others (i.e., the Internet).
- Portals provide web access to internal systems.
- Network computers (thin clients) are like Web terminals.
- Mobile computers interconnect via wireless networks.
- Networking becoming ubiquitous –even home systems use firewalls to protect home computers from Internet attacks.

# Computing Environments

## Mobile Computing

- Hand-held smart-phones, tablets, etc.
- What is the functional difference between them and a “traditional” laptop?
- Extra feature — more OS features (GPS, gyroscope).
- Allows new types of apps like augmented reality.
- Use IEEE 802.11 wireless, or cellular data networks for connectivity.
- Leaders are **Apple iOS** and **Google Android**.

# Computing Environments

## *Distributed Systems*

- Collection of separate, possibly heterogeneous, systems networked together.
  - Network is a communications path, TCP/IP most common.
    - » Local Area Network (LAN)
    - » Wide Area Network (WAN)
    - » Metropolitan Area Network (MAN)
    - » Personal Area Network (PAN)
- Network Operating System provides features (such as file sharing) between systems across network.
  - Communication scheme allows systems to exchange messages.
  - Illusion of a single system.

# Computing Environments

## Client-Server Computing

- Dumb terminals supplanted by smart PCs.
- Many systems now **servers**, responding to requests generated by **clients**.
  - Compute-server system provides an interface to client to request services (i.e., database).
  - File-server system provides interface for clients to store and retrieve files.

# Computing Environments

## Peer-to-Peer Computing

- Does not distinguish clients and servers.
  - Instead all nodes are considered peers.
  - May each act as client, server or both.
  - Node must join P2P network.
    - » Registers its service with central lookup service on network, or
    - » Broadcast request for service and respond to requests for service via discovery protocol.
  - Examples include Napster and Gnutella, Voice over IP (VoIP) such as Skype .

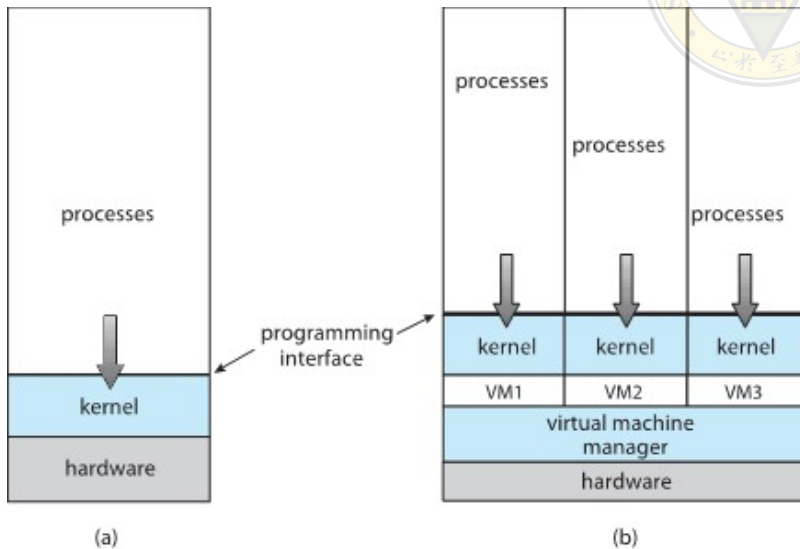

# Computing Environments

## Virtualization

- Allows operating systems to run applications within other OSes.
  - Vast and growing industry.
- **Emulation** used when source CPU type different from target type (i.e. PowerPC to Intel x86).
  - Generally slowest method.
  - When computer language not compiled to native code — **Interpretation**.
- **Virtualization** — OS natively compiled for CPU, running guest OSes also natively compiled.
  - Consider VMware running WinXP guests, each running applications, all on native WinXP host OS.
  - **Virtual machine manager (VMM)** provides virtualization services.

# Computing Environments

## Virtualization (contd.)

# Computing Environments

## Cloud Computing

- Delivers computing, storage, apps as a service across a network.
- Logical extension of virtualization because it uses virtualization as the base for its functionality.
- Many types:
  - **Public cloud** — available via Internet to anyone willing to pay.
  - **Private cloud** — run by a company for the company's own use.
  - **Hybrid cloud** — includes both public and private cloud components.
  - Software as a Service (**SaaS**) — one or more applications available via the Internet (i.e., word processor).
  - Platform as a Service (**PaaS**) — software stack ready for application use via the Internet (i.e., a database server).
  - Infrastructure as a Service (**IaaS**) — servers or storage available over Internet (i.e., storage available for backup use).

# Computing Environments

## *Real-Time Embedded Systems*

- Real-time embedded systems most prevalent form of computers.
  - Vary considerable, special purpose, limited purpose OS, **real-time OS**.
  - Use expanding.
- Many other special computing environments as well.
  - Some have OSes, some perform tasks without an OS.
- Real-time OS has well-defined fixed time constraints.
  - Processing must be done within constraint.
  - Correct operation only if constraints met.

## Open-Source Operating Systems

- Operating systems made available in source-code format rather than just binary closed-source.
- Counter to the copy protection and Digital Rights Management (DRM) movement.
- Started by Free Software Foundation (FSF), which has “copyleft” GNU Public License (GPL).
- Examples include GNU/Linux and BSD UNIX (including core of Mac OS X), and many more.
- Can use VMM like VMware Player (Free on Windows), Virtualbox (open source and free on many platforms - available @ <http://www.virtualbox.com>) .
  - Use to run guest operating systems for exploration.
